Turn Browser Traces Into Reusable Agent Clients

By Coding Agents Alpha Tracker • July 20, 2026

A browser-agent technique turns one recorded web session into a reusable client, while Kody's latest release adds an event-driven path for routing coding-agent feedback to Discord.

TOP SIGNAL

Use browser automation once to capture the network contract, then promote it into a reusable client. @thdxr, sharing a technique from @jlongster, recommends having an agent record a HAR file and derive a client from it instead of repeatedly controlling a browser; he used the approach to build a quick Uber Eats CLI. [1] Kent C. Dodds frames this promotion from ad-hoc agent work into durable, deterministic, composable software as a core strength of Kody. [2]

TRY THIS

- **Replace repeat browser-driving with a HAR-to-client pass.**
 1. Ask the agent to complete the browser flow once while recording network requests into a HAR file.
 2. Ask it to derive a client for that site from the captured requests.
 3. Use the client for subsequent calls rather than having the agent operate the browser each time. [1]
- **Create an agent-feedback relay to Discord with Kody.** Ask your coding agent to “send feedback to @kodykoala.” That submission triggers an event; with your own Kody instance subscribed, the event can be forwarded to Discord. [3]

WHAT SHIPPED

- **Kody v2026-07-19** adds agent-submitted feedback addressed to @kodykoala, enabling the event-driven relay workflow above. Release

notes [3]

GO DEEPER

- **Kody v2026-07-19 release:** Inspect the feedback mechanism if you want to connect coding-agent output to an event subscriber and Discord notification flow. [3]

Editorial take: the durable agent pattern is to capture one-off interactive work, turn it into a reusable interface, and route exceptions or feedback through explicit events—not repeated manual browser control. [1, 2]
